

Which of Meera's three numbers is real?

Kalpa Retail's CEO asks before Monday's growth review: is the Retail-Plus fall real, is Student's 40 percent worth budget, and did the monsoon sale work?

1 Which check does each of Meera's three questions need?

Meera Raghavan's three numbers are a fall per member in Retail-Plus, Kalpa's paid membership tier, a 40 percent rise in Student orders, and a 6 percent lift Marketing credits to the monsoon sale. A gap gets a chance reference that fits how the data was collected, a rate gets the count behind it, and a campaign gets a fair comparison. Each check ends as one line of the note, which Kavya Nair, the team's senior analyst, reviews before Meera sees it.

Crux. A p-value is a share of chance-only worlds; it is never the chance the finding is wrong.

2 Which method fits each of the day's six questions?

Question	Best fit here	Second check	Switch when
Real or wobble?	Flip each member's pair	Exact count; paired test	Different customers
Worth acting on?	Rupees against company and cost	Members' own falls, redrawn	A known recovery rate
Trust a rate?	Coin flips on its count	Every deal counted	A cheap way to reach customers
Did a discount work?	Split inside each segment	Both groups on one mix	Groups chosen by a coin
What goes to the CEO?	Four-part note, under 200 words	The day's rules, applied again	The same review every week
Did the sale cause it?	Random hold-back, next time	Months with no sale	A hold-back is refused

3 Flip or shuffle, and what does the share let you say?

The same members measured twice: flip each member's own pair. Different customers in each group: shuffle the group labels.

```
d = [a - b for a, b in zip(q1, q2)]
gaps = [mean([x if random.random() < .5 else -x
              for x in d]) for _ in range(5000)]
one_way = sum(g >= real for g in gaps) / 5000
either = sum(abs(g) >= abs(real) for g in gaps) / 5000
```

Draft	Survives Kavya
"A 3 percent chance we are wrong."	"If nothing had changed, a fall this large turns up in about 3 of 100 flips, 6 either way."
"p = 0.72 proves nothing changed."	"The gap sits inside the usual wobble."

4 Is a gap that beats chance worth acting on?

A small share says a gap beats chance and nothing about its size: with enough orders even Rs 20 comes back significant. Size it against the company's quarter, then against the cost: an assumed Rs 11,000 offer on a Rs 24,420 fall pays only above 45 percent recovery. If the range dips below the cost, test on part of the group first.

Crux. Real and worth acting on are two separate calls: a chance reference answers the first, rupees against cost answer the second.

5 When is a rate too thin to act on?

Behind the rate	One more moves it by
10	10 points
30	3.3 points
100	1 point
400	0.25 points

Count the customers as well as the orders: thirty orders from three customers are three customers' habits. A rate on fewer than thirty customers is a lead, one to watch until more customers buy. Flip a coin per order, thousands of times, and see how often chance alone makes the rise.

Crux. Count what a rate stands on, in customers as well as orders, before you repeat it; under thirty customers, it is a lead.

6 How can an average rise while every segment falls?

The blend, one average over both segments mixed together, rises when the group that got the campaign holds more of the segment that spends more anyway. Compare inside each segment, state the two groups' mix, and put both on one mix for a one-line answer. At 15 percent off, volume must rise 17.6 percent for revenue to stand still.

Crux. Split an aggregate by segment before you credit a campaign, and name who got it.

7 What must each line of Meera's note carry?

Claim: one sentence she can act on. Evidence: the number with its base and its count. Caveat: what would change the claim. Action: what to do next and what it costs. Each line must carry a base, a count or chance, and a caveat.

Crux. The note is claim, evidence, caveat, action, and "not yet, and here is what would tell us" is a complete answer.

8 What makes a campaign comparison fair?

Before and after credits the campaign with the month. Put an untargeted segment beside it, count the orders under each month, run the same test on months with no sale, and decide the next campaign's groups with a coin, inside each segment, before it starts.

Crux. A fair comparison asks who got it, who did not, and what else changed; only a coin makes the two groups alike.

THE WORDS ON THIS SHEET

- Chance reference** The gaps chance alone makes when nothing changed, which a real gap is read...
- Flip test** A coin per member decides which of its two quarters counts as Q1
- Label shuffle** Dealing group labels at random across different customers
- p-value** Share of chance-only worlds with a gap at least as large
- Break-even recovery** Share of a fall a fix must win back
- Lead** A rate on under thirty customers
