

The investigation ladder

Kalpa Retail, Week 1 Tuesday. A drop is investigated in six chapters, and each answers a question that has to be settled before the next one is worth asking. The tree beside the ladder carries the closed quarters, Q1 against Q2, on booked orders as exported.

1 The ladder beside the tree

Revenue fell 11.0 percent on closed quarters: 1.000 times 0.754 times 1.180 is 0.890. In behaviour the fall sits in Retail-Plus, where the same 22 members placed 26 orders against 51.

Crux. A rate without its denominator is a rumour.

2 Windows, like with like

Window	Result	Verdict
Q1 against Q2 cut at 15 Sep	Down 25.9 percent	First and last dates show 13 weeks against 11.
Closed quarters, 13 weeks each	Down 11.0 percent	It is fair once Q2 has closed.
Per week, Q2 still open	Down 12.4 percent	A rate makes it comparable.
Second route, by month	Down 11.0 percent	The dates agree with the quarter field.

Crux. Confirm the drop on matched windows before you explain it.

3 The tree, as a bridge in rupees

Step	Rupees
Q1 revenue	Rs 2,10,00,000
Customers, 69 to 69	Rs 0
Orders per customer, 28 fewer orders	Minus Rs 51,57,895
Revenue per order, Rs 33,231 more on 86	Plus Rs 28,57,895
Q2 revenue	Rs 1,87,00,000

Crux. Decompose along the tree: customers, orders per customer, revenue per order.

4 Missing is unknown

```
order.get("discount", 0) # a decision that looks like no decision
```

Read as zero, a blank counts as "no discount", so 50.0 percent of Q2's orders seem to carry one. Split the rest into recorded zeros and blanks, report the share where recorded, 71.7 percent, with the range the blanks allow, and bound the branch: Rs 150 on 86 orders is at most Rs 12,900.

Crux. Missing means unknown until someone chooses a default and writes down why.

5 Roll-up with weights, and mix against rate

A function beats eight copied loops. A plain average of four segments gives 1.94 and 1.82; total orders over total customers gives 1.65 and 1.25. Revenue per order rose Rs 33,231, and about 69 percent of it is mix, because small Retail-Plus orders fell from 44.7 to 30.2 percent of orders.

Crux. Roll a rate up with its weights; never average the averages.

6 Functions return

```
def tree_for(rows):
    ...
    return {"revenue": revenue, "orders": n, "customers": c}
```

A helper that prints for large changes returns `None`, and the filter drops it: four segments go in and two come back as `None`. Check with `None in changes.values()`. The id overlap answers Marketing's churn claim: 69 in both quarters, 0 lost, 0 new.

Crux. A function returns its answer; count the groups in and the groups out.

7 Hypothesis with evidence

Test	What the file shows
Timing	Retail-Plus fell from July, before the late-August break the complaint dates.
Channel	Web, store and app all fell, so the app did not fall first and alone.
Ceiling	At the pre-break pace the button explains at most about 4 orders.
Evidence to ask for	The app's reorder logs by week, the release date, and the tier's change log.

Crux. Name the cause as a hypothesis, with its ceiling and the evidence that would settle it.

THE WORDS ON THIS SHEET

Matched windows Two periods of the same length compared, or both turned into a rate

Rate A numerator over a denominator in a stated window

Like-for-like A comparison that holds the outlets, the weeks and the weekends equal

Decomposition A change split along the tree into branches that multiply

Bridge A change in rupees moved one branch at a time from start to end

Middle half The spread between the first and third quartiles of the sorted values

Default The value used when a field is absent, with its written reason

Function A named block that takes inputs and returns one answer
